Six finite worksheets: implementation packet

Source preparation, 18 October 2026. No frozen worksheet or scientific trial executed. Authority: TASK-20261018-1cb336; two separate native RUNs per contract remain required after Coordinator publication/admission.

Scope. 95f69f: low-bit addition images. c9110e: one F11 generalized Weierstrass curve and involution witnesses. c9c5a4: two eight-node functional graphs and rational bounds. d68ac9: two known-multiple windows on one F151 curve. efafc0: one F17 chord and control. f7310e: two integer cancellation rows. No attack cost, speedup, large-field transfer, formal proof or ECDLP certificate is claimed.

Preserved negatives and ambiguity. The original efafc0 third-intersection/sum prediction is retained even if false; independently agreeing arithmetic and passing controls remain valid with prediction match false. For c9c5a4, both $\min(D, \tau)$ and $\min(D + 1, \tau)$ are explicit, with D the cap and τ the hitting distance. Original predictions and the definition gap remain visible. The additive interpretation must be admitted before a trial. Integer-only seed in the separate JSON schema remains a documented discrepancy; no seed is invented.

Evidence. Native compile/synthetic receipts are retained under synthetic-checks and synthetic-checks-v2. Raw scientific output does not exist. The final implementation receipt records all source and binding hashes. Future trials will retain byte-exact primary stdout, an independent native recomputation, explicit controls and separate prediction comparisons.
