Formal target pointer coverage at 2165804a

2026-10-30 UTC. This is syntactic navigation evidence from Git commit `2165804a` (full ID in `inventory.json`). It is not a theorem, claim-fidelity review, experiment replay, or performance result.

Observation. The frozen tree has 2,790 experiment directories and 91 registered formal target YAMLs. Six experiment IDs have exact standalone EXP-ID pointers in a registered target, declared source, or theorem source; 2,784 have none. Twenty target YAMLs link an exact experiment ID; 71 do not. The graph uses separate denominators and does not show proof coverage.

Method. `build_inventory.py` reads the frozen Git tree with `git ls-tree` and `git show`, then records scanned path and SHA-256 for each literal witness. Full counts, linked IDs, hashes, tree IDs, and the reproduction command are in `inventory.json` and `report.md`.

Defect and limit. The scoped-odd-torsion target names `Torsion.lean` in `formal/ScopedObstructions/`, absent at this commit. This is a traceability defect; a related theorem may exist elsewhere. The pointer count certifies no Lean type, build, historical run, or scientific claim. Independent statement-to-claim review and empirical replay remain required.
