Additive environment-metadata correction

Date: 2026-10-23 UTC. **Applies to:** report.md and report.pdf at commit `1cd35e7371f27a0f2bfe52cad6b9ddd8f9ff5131`. The original report and factor receipts remain unchanged.

The sentence in the report's **Completed twist factorizations** section saying that software versions are preserved in the two factor receipts is too broad. The `gp_version` field in each receipt is empty. The exact factor commands, stdin, stdout, stderr, process status, elapsed wall time, host, script digest, input digest, factors, and product check *are* preserved there. The runner used `gp --version` but stored only its stdout; this GP installation writes its version banner to stderr.

gp_environment_correction.json, produced by capture_gp_environment.py, binds each immutable factor receipt by SHA-256. A **post-run** check observed PARI/GP 2.17.3 at `/opt/homebrew/Cellar/pari/2.17.3/bin/gp-2.17` and recorded its binary SHA-256 `1b3464452036a97072a2514f5094bb49188e2ee3089a61514443494f4875ceb5`. That check does not establish the exact binary identity at the earlier factor calls. The separate Sage verifier records Sage 10.10.rc0 and rechecks the factors with proof-enabled primality tests and the full twist-order products. Sage may use PARI libraries internally, so these checks are not a claim of independent primality algorithms.

Unchanged arithmetic conclusion: Both reported factorizations multiply to their exact quadratic-twist orders, and their largest prime factors have 147 and 140 bits. The correction changes provenance precision, not the factor values or the selection-rule result. It adds no historical generator trace or ordinary-group attack.
