Verifier integration: V6 addendum

2026-10-25 · Static/mocked engineering observations only

Named orders executed: 0. Legacy programs executed: 0.

Capture	Syntax exit	Methods	Errors	Original-call attempts
V4	0	7	23	0
V6	0	9	29	0

The errors cascade from early gates; they are not independent curve observations. V4 stopped at the published P-224 coefficient. Its exact prior certificate already existed under side=other. V6′s dedicated full producer/checker metadata test now passes for all 21 UIDs, with the exact coefficient and prior certificates retained.

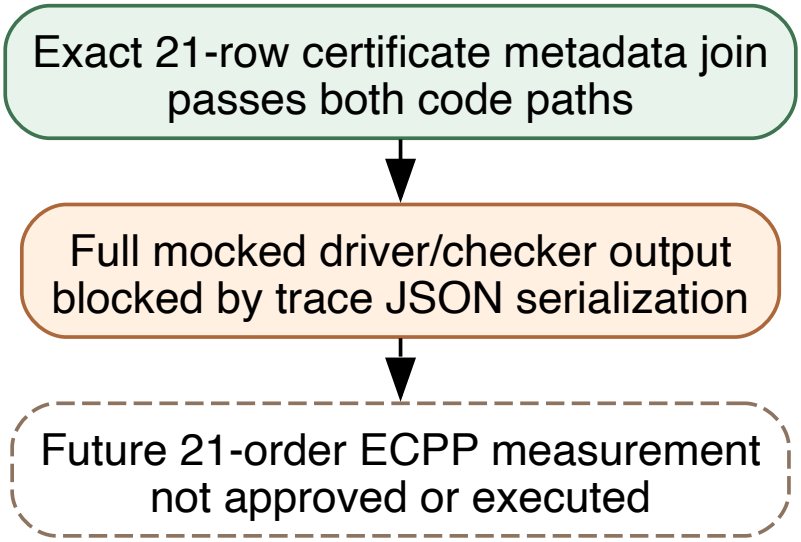

Figure 1: Current scope. Dashed edge remains prospective.

V6 cannot serialize the observation: a raw bytes catalog-factor token remains inside its trace. The static diagnostic locates it in the already archived non-cohort prime101 control. The same object also blocks the exception envelope. Both parsers need explicit consistent JSON-safe factor types; raw serial and catalog bytes remain unchanged.

V5 omitted the rebuilt test module; it had no full-suite run. A separate metadata-only probe found a corpus-header parsing defect. V6 and its V7 parser patch are separate retained artifacts. Version numbers identify proposals and actual guarded captures, rather than independent replications.

The implementation remains unready. A new immutable full mocked capture is next. Passing it establishes implementation readiness only. Separate archival, a frozen scientific packet, actual preapproval, committed approval and ready state still precede any cohort execution. Historical visitation, selection criteria and shared mathematical weakness remain unknown. No mathematical frontier graph changes.

Evidence: source-bindings.json gives exact paths and SHA-256 values for the V4/V6 actual receipts and logs, V5 metadata diagnostic and V6 trace diagnostic under BATCH-08d006. The raw receipts retain Python/platform versions, source hashes, actual counts and guard results.
