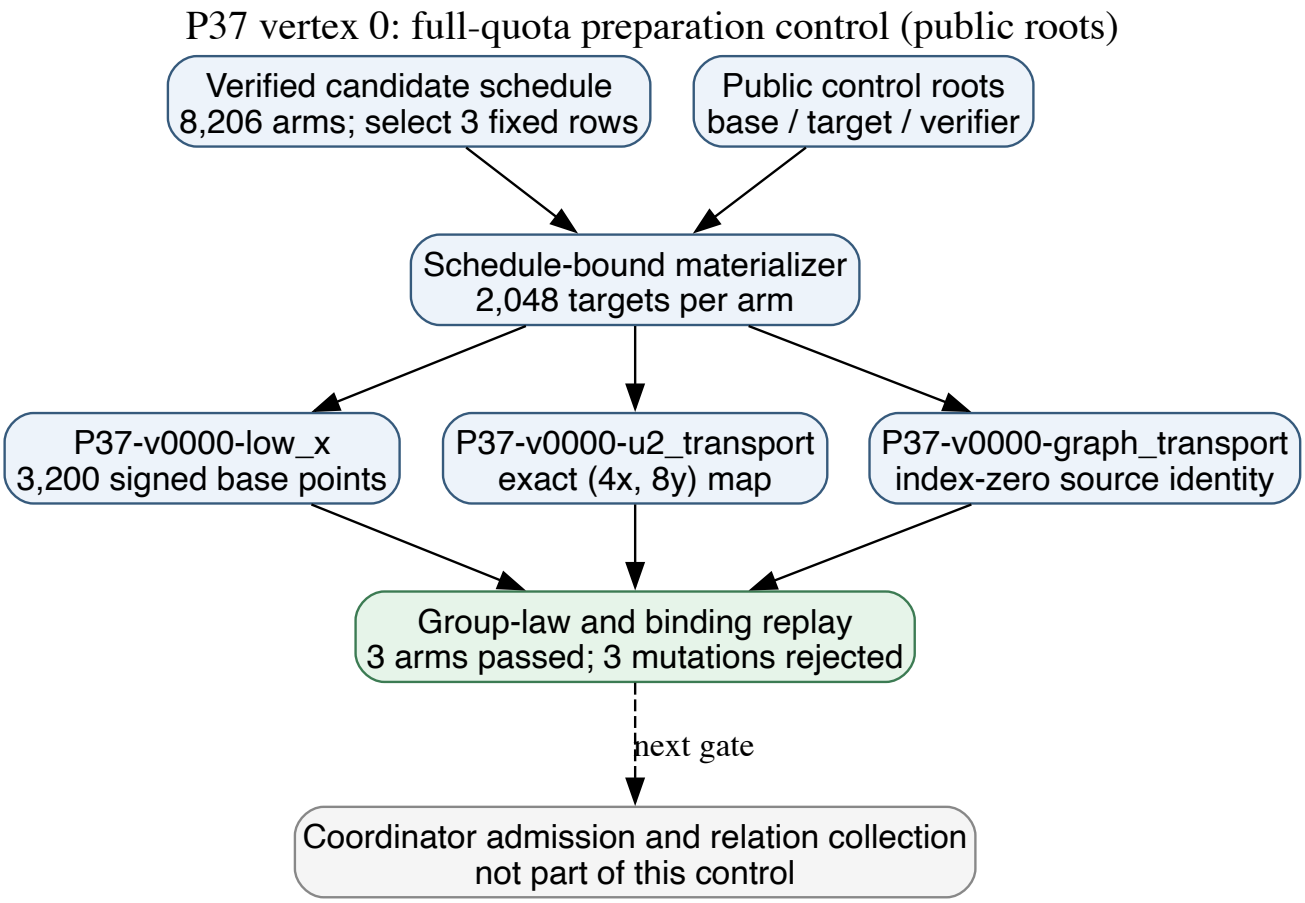
1. Full-quota P37 graph input preparation control

2026-10-22, Conductor task T-4822. Implementation control at P37 vertex 0 using public roots. This report records preparation and replay observations; it makes no relation-yield, rank, ECDLP-cost or hypothesis-status decision.



The independently checked candidate schedule contains 8,206 arms. The new materializer selected three named P37 vertex-zero arms and prepared the full discovery quota of 2,048 targets for each. Each arm contains 3,200 signed base points. The native and graph-transport input bytes are identical at the source vertex. The separate u=2 transported input matches the exact (x,y) -> (4x,8y) map on all base and target points. The coefficient stream digest agrees across all three arms. The existing group-law verifier passed on every saved input; swapped-root, unscheduled-arm and changed-target controls were rejected.

The raw inputs, manifests, bindings, measured preparation process durations, and machine checks are retained in `control/`. The roots are public control values and are excluded from scientific discovery. The group-law verifier did not independently replay the seed stream; the materializer reconstructed every coefficient from the three roots. Relation collection, rank, confirmation and complete ECDLP costs remain unmeasured by this control.

Next: freeze scientific roots and the runnable experiment contract, issue a Coordinator admission, and execute the fixed graph schedule through `run`.
