Outer Git control: source-only recovery

EXP-ECDLP-53b1c3; 18 October 2026. New outer metadata identity reuses unchanged 615fcf scientific inputs/helper/C++/criteria. Old route A checker stderr records Git status exit 128, unable to create threaded lstat; final manifest was not written and route B was not launched. That partial attempt is retained, not converted into a mathematical negative or completed pair. This handoff launches no frozen scientific cell.

Explicit prospective environment. `GIT_CONFIG_COUNT=1`, `GIT_CONFIG_KEY_0=core.preloadIndex`, `GIT_CONFIG_VALUE_0=false` are recorded in the *outer* supervisor process environment. Native child argv remains exact direct absolute Python plus byte-identical helper, without an env prefix or interpreter flag. The 1GiB process ceiling and scientific parameters are unchanged.

Actual synthetic subprocess controls. The unchanged helper runs in a disposable isolated Git checkout with unrelated tiny C++ fixtures and explicitly synthetic provenance. Direct primary and independent checker, effective Git configuration false and real Git status all pass under 1GiB. The original env-prefix negative control still refuses before native compilation. Temporary fixture-only Git commits were explicitly authorized; no shared AR repository commit/push occurs. This is not production native admission, scientific evidence, arithmetic certification or model proof. Fixture success does not guarantee full-repository resource stability.

Immutable boundary. Config changes only outer identity/specification/ source-dependency metadata; all 28 protected old source/config/spec/plan/test/ failed-output files verify unchanged. New canonical mutable spec is outside source closure; mandatory plan specification digest binds final approval bytes separately. Two primary RUN placeholders, independent recomputation, original predicates, null seed and certificate none remain intact.

Remaining work. Coordinator publication, review/approval/freeze, ordinary native source/plan/claim admission and actual paired execution. No canonical protocol/queue/status change or mathematical/performance graph promotion follows from this packet.
