Gamma-bound binary m8 successor: sorted summands

Design record, 2026-10-18. EXP-ICPERF-554db4 is review_required; no scientific solver call is authorized.

The predecessor's two planted solver calls each reached their 300-second wall cap. Its 64 natural calls did not start. The successor first binds gamma as the unique fourth root of b=31 in GF(2^61), numeric 70364449406991, and requires an independent blind derivation of eight targets and 32 raw channels before comparison with archived manifests.

The proposed solver representation sorts eight 11-bit summand coordinates and re-chains six intermediate full-point sums. Group commutativity preserves a certified point relation under permutation, but finite XCNF fidelity and any runtime effect remain unverified. Two B=316 bases each receive an unsorted/sorted/unsorted planted-positive schedule. The identical unsorted repeat supplies an A/A timing spread. Every call has a 1200-second and sampled-8-GiB guard; six calls are the prospective maximum.

The sorted-to-cost edge is conjectural. The two planted targets differ, so no cross-base yield comparison is valid. Input and implementation controls, independent blind review, a complete preapproval packet, a new approval decision and normal run admission remain open. Natural relation yield, useful rank, degree of regularity, linear algebra, target work, complete end-to-end cost and matched rho are unmeasured by this design.

Sources: EXP-ICPERF-018b0c; RUN-ICPERF-712e85; EV-ICPERF-54ac6b; DEC-20261017-3b87bf; problems/icperf-k11-gamma-admission-unbound.md. Provenance: internal for archived observations, derived for the point-sum permutation argument. The complete mechanism and controls are in the accompanying Markdown report and prospective specification.
