Prime63 planted-positive contradiction guard

GOAL-ICPERF-e6b6a4 • 2026-10-17 • engineering control

The archived producer flags a planted positive whose solver response is `certified_no_solution` as an invalid control and stops the panel. A self-consistent raw archive with that response, however, passed the archived independent checker as a censored positive. That is a checker acceptance defect at the evidence boundary.

The additive `guard.py` first runs the archived checker, then independently evaluates every planted witness against the exact polynomial, base, signed-lift and full-target-point conditions. It reads the canonical raw archive and rejects a planted `certified_no_solution` response. A model-cap response remains censored. Archived sources remain byte-for-byte unchanged.

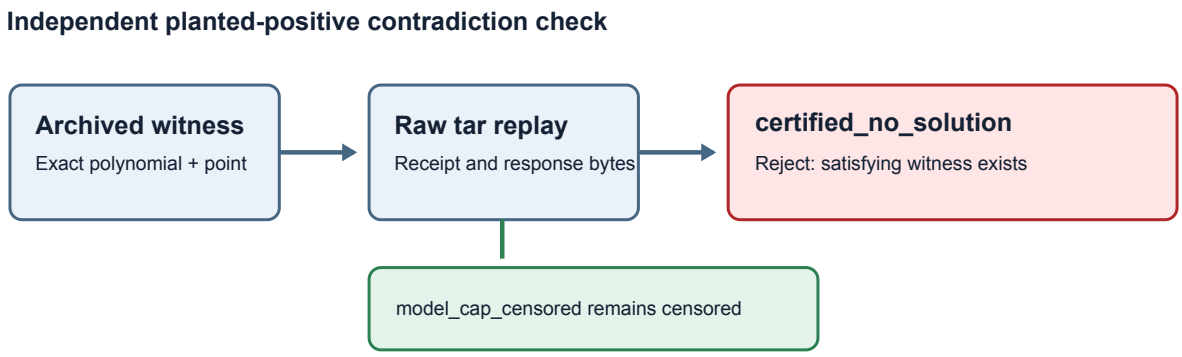

Figure 1: Additive contradiction guard. The red response is rejected after independent witness replay.

Engineering control

A synthetic Git fixture over a 101-element prime field used no Sage calls. The forged, internally consistent unit-ideal response passed the old checker as censored and was rejected by the guard. The model-cap control remained censored. The exact command in `command.txt` ran eight tests, including the archived admission and raw-custody controls. Logs and hashes are retained in this directory. An unrelated existing `ResourceWarning` appears in stderr.

The result is a scoped checker fix. No full-width solve, relation yield, degree of regularity, useful rank, target work, matched rho or complete index-calculus runtime was measured. The scientific experiment remains `review_required` until the successor source and execution protocol are hash-bound and pass preapproval.
