P37 vertex 24 public targetwise count control

Observation-only report, 2026-10-21. These fixed public targets are excluded from discovery and confirmation inference.

Identity and method

P37 over $F_{81640512137}$, prime group order 81640511861. The signed source base has 3,200 points and is transported through 24 saved degree-7 edges. The independent chain verifier replayed 76,800 point images. Both endpoints use the earlier fixed 128 public scalar labels and the same exact ordered-count oracle.

Observations

All 128 targetwise counts agree. Seven targets are nonempty and have 48 ordered relations total. Source and transported count files have the same SHA-256: `f799d1cd80cdacd125d4ad0e1681ce5e704da836c569b3e12b11763ba144d473` . The same digest appears in the earlier first-check P37 source control. The saved destination checkpoint SHA-256 is `ed74a5492453944588f3365e483cc28a634e39bf5be6b5ca48006ae2f751b93a` .

Figure 1: Exact ordered three-point counts for the same 128 public targets on source and vertex-24 transported bases. Bars coincide targetwise.

Scope

This is an implementation control for this fixed stream and endpoint. The admitted discovery stream, native-base comparison, useful-rank replay and full ECDLP cost measurements remain open. Inputs, commands, binary/source hashes, raw counts, meters, and a retained failed wrapper attempt are in the accompanying Markdown report.
